Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
•00	0000000	000	0000000	00

Can investors value investment options correctly?

- Central question in financial economics: Can investors correctly value financial assets?
- Behavioral economists argue that various assets are systematically mispriced
- **Our goal**: Understand whether misvaluation of equities is partially due to investors' inability to correctly price investment (growth) options

・ロト ・ 同ト ・ 国ト ・ 国ト

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
000	0000000	000	0000000	00

Important Question

- **Important**: Growth options are the most important component of the firm value
 - ► Especially now, given the changing nature of the economy and the importance of growth firms: more firms in S&P 500 are growth-oriented than ever before
- But they are **difficult to value**:
 - **1** Difficult to project cash flows of a growth firm think Snap Inc.
 - 2 Risk of the firm changes as options are exercised
- Usual valuation techniques DCF, multiples are inappropriate

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
000	0000000	000	0000000	00

- **1** Construct simplest possible real options model of a firm with investment (expansion) options
 - Most related to Pindyck (1988) and Abel and Eberly (1996)

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
000	0000000	000	0000000	00

Model Setup

- A firm is infinitely lived
- Its capital stock at time t is K_t
- It has a continuum of expansion options:
 - For a fixed price η per unit of capital it can purchase and install additional capital
- Capital depreciates at a rate λ per unit of time
- The firm's instantaneous profit is $\pi(K_t, x_t) = (1 \tau) x_t K_t^{\theta}$
 - ▶ $0 < \theta < 1$ is the curvature of the production function
 - au is the corporate tax rate
 - Demand x_t follows a geometric Brownian motion process: $dx_t = \mu x_t dt + \sigma x_t dB_t$

Optimal Investment

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ●

	iciusion
000 0000000 000 000 000	

Solution: Firm Value

• The optimal firm value can be decomposed into 2 parts:

Value of Assets In Place:

$$\mathsf{AP} = \frac{x_t K_t^{\theta} (1 - \tau)}{r - \mu + \lambda \theta}$$

Value of Growth Options:

$$\mathsf{GO} = \left[\frac{(1-\tau)\theta}{\beta_1 \left(r-\mu+\lambda\theta\right)}\right]^{\beta_1} \left(\frac{\beta_1-1}{\eta}\right)^{\beta_1-1} \frac{K_t^{\beta_1(\theta-1)+1}}{\beta_1(1-\theta)-1} x_t^{\beta_1}$$

- ★ subject to the condition: $\theta < 1 \frac{1}{\beta_1}$

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
000	0000000	000	0000000	00

Caveats

- The model is not very realistic
 - It ignores financing decision
 - It ignores feedback effects from misvaluation to real option exercise
 - It ignores competition among firms
- Lack of realism is due to two reasons:
 - We need to be able to solve the model in closed form
 - We want to see how far the simplest possible model can take us before moving to more sophisticated ones

Motivation Estimation Results Stock Returns	Conclusion
000 0000000 000 0000000	00

Estimation I

For given values of

- Curvature of production function, θ
- Cost of installing new capital, η

we compute a theoretical firm value of each firm every month, $V_{it}(\theta, \eta)$ and compare it to the firm's pseudo-market value, \tilde{V}_{it} , which is the sum of the value of equity and value of debt

ELE SOG

イロト イポト イヨト イヨト

 - Cost of installing new capital, η

we compute a theoretical firm value of each firm every month, $V_{it}(\theta, \eta)$ and compare it to the firm's pseudo-market value, \tilde{V}_{it} , which is the sum of the value of equity and value of debt

• Misvaluation is defined as $\epsilon_{it} = \tilde{V}_{it}/V_{it}(heta,\eta)$

• Firms with ϵ_{it} above/below 1 are overvalued/undervalued

・ロト ・ 同ト ・ 三ト ・ 三ト

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion

Estimation II

• θ_{jt} and η_{jt} are chosen to minimize for each industry-month mean log misvaluation in the past 12 months:

$$(\hat{ heta}_{jt}, \hat{\eta}_{jt}) = \operatorname{argmin} \sum_{i=t}^{t-12} \sum_{k=1}^{N_{jt}} |\log \epsilon_{kt}|$$

- This assumes industries are valued correctly on average
- The optimization is done subject to the constraint: $\theta < 1 \frac{1}{\beta_1}$
- If the firm's capital is outside its optimal investment boundary, $x_{it} > X(K_{it})$, we assume that the firm immediately invests optimal amount
 - $\star\,$ This happens in 6% of cases; the results are robust to excluding these

Motivation	Empirical Approach	Estimation Results	Stock Returns	Conclusion
000	0000000	000	0000000	00

Hypotheses

lf:

- Investors cannot price growth firms, AND
- It leads to misvaluation in equity markets, AND
- Misvaluation is temporary and is gradually corrected

Then:

- H1a: Undervalued firms are expected to have higher future returns
- H1b: Misvaluation should get corrected at reasonable horizons
- H2b: The difference in future returns is larger for GO firms than for AP firms
- H2a: The difference in future returns would not exist in a counterfactual model that does not account for the value of GOs

Conclusion

- Investors misprice growth-oriented firms because GOs are hard to value
- Important to understand why:
 - What tools do analysts use for these firms?
- Policy implication: Market participants need to be aware of this fact.
 - Investment community need to discuss more appropriate tools how to value growth firms
- Redistribution of wealth from regular investors (index funds) to more sophisticated hedge funds

E Sac

・ロト ・ 同ト ・ 国ト ・ 国ト

Solution: Optimal Investment

- Optimal investment policy:
- Purchase and install an infinitesimally small amount of additional capital as soon as x_t reaches investment threshold $X(K_t)$
- The investment threshold is

$$X(K_t) = \frac{\beta_1}{\beta_1 - 1} \frac{(r - \mu + \lambda\theta)\eta K_t^{1-\theta}}{(1 - \tau)\theta}$$

 \blacktriangleright Increases in $K_t:$ a better capitalized firm optimally waits longer, until a higher realization of x_t is reached

Comparative statics

Lyandres Matveyev Zhdanov, (c) 2017

Comparative statics

Identification

• The cost of installing new capital, η , is identified through the value of growth options only:

$$\left[\frac{(1-\tau)\theta}{\beta_1\left(r-\mu+\lambda\theta\right)}\right]^{\beta_1} \left(\frac{\beta_1-1}{\eta}\right)^{\beta_1-1} \frac{K_t^{\beta_1\left(\theta-1\right)+1}}{\beta_1\left(1-\theta\right)-1} x_t^{\beta_1}$$

• The curvature of production function, θ , is identified from the value of assets-in-place:

$$\frac{x_t K_t^{\theta} (1-\tau)}{r - \mu + \lambda \theta}$$

as well as through the value of GOs.

Estimation: Accounting for industry misvaluation

- The assumption in the above estimation procedure is that industries are correctly priced on average at any point in time
- This is too restrictive industries may be misvalued
- To estimate it, we follow the procedure in Rhodes-Kropf, Robinson and Viswanathan (2005)

Back to Estimation

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□▶

Estimation: Accounting for industry misvaluation

• Estimate RRV regression in year t in each industry:

 $\log(\mathsf{ME}_{it}) = \alpha_0 + \alpha_1 \log(\mathsf{BE}_{it}) + \alpha_2 \log(|\mathsf{NI}_{it}|) + \alpha_3 \mathbb{I}(\mathsf{NI}_{it} < 0) + \alpha_4 \mathsf{Lev}_{it} + \epsilon_{it}$

- Predicted firm value from this regression is the current firm value assuming it's valued as an average firm in the industry
- Compute the same but for years [t-5,t-1]
 - Predicted firm value from this regression is the current firm value assuming it's valued as an average firm in the industry give the data
- Industry misvaluation in a given year is the misvaluation of a median firm in the industry in that year
- We then minimize the following objective function:

$$(\hat{\theta}_{jt}, \hat{\eta}_{jt}) = \operatorname{argmin} \sum_{\tau=t-12}^{t-1} \left(\sum_{\nu=1}^{N_{jt}} |\log \epsilon_{\nu\tau}| - \operatorname{median}(\log \epsilon_{j\tau}) \right)$$

Back to Estimation

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ●

Parameter Persistence

• The θ and η estimates are relatively stable

Lag	% abs. change in $ heta$	% abs. change in η
1	4.8%	2.3%
3	9.5%	4.3%
6	14.4%	6.5%
12	21.0%	9.4%
24	27.0%	12.6%
36	28.3%	13.8%

H1a: Robustness

- Robust to various definitions of undervaluation/overvaluation
 - Quintiles of misvaluation
 - Binary classification (undervalued vs overvalued)
- Robust to equally-weighted returns
- Robust to changes in estimation assumptions
 - ► Estimation using only firms with above-industry-median analyst coverage
 - Estimation using SIC or NAICS industry definitions
 - Estimation using John Graham's marginal tax rates
- Robust to various return horizons (with gradual decay)
- Stronger in NBER recessions than in expansions
